# CSCI 3753 Design & Analysis of Operating Systems

Introduction

Lecture Notes By
Shivakant Mishra
Computer Science, CU-Boulder
Last Update: 08/29/2017

### Operating Systems

- OS is an essential (and perhaps the most important) part of a computing system
  - PCs, laptops, supercomputers, cloud, data centers, cell phones, PDAs, tablets, embedded devices, ...
  - Controls the operation of hardware components
    - Allows sharing of various computing components
  - Provides a usable interface
- One of the largest piece of software
- Examples: Windows, Linux, Mac OS X, Google Android, iOS, ...
  - More than 500 OSes listed at http://www.operatingsystem.org/betriebssystem/\_english/os-liste.htm

# What is an Operating System?

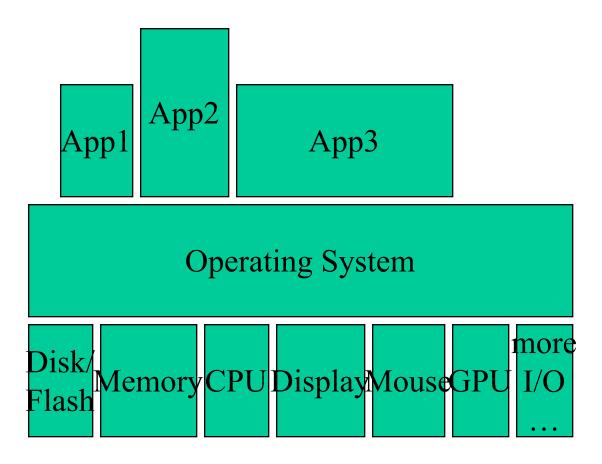

An operating system is a layer of software between applications and hardware that provides useful services to applications

**Applications** 

**Operating System** 

Hardware

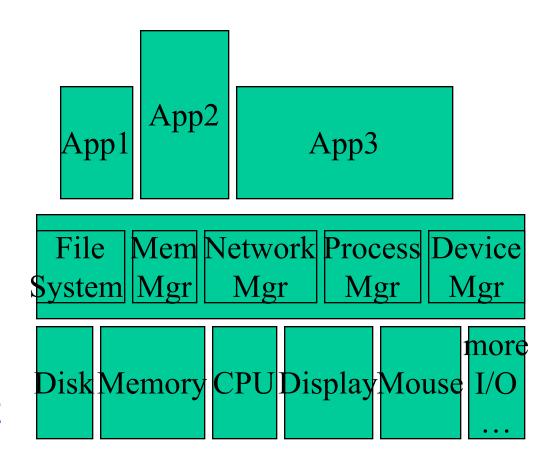

### What is an Operating System?

Other devices include: wired network card, WiFi, camera, microphone, audio output, keyboard, DVD/CD, USB, etc.

### What is an Operating System?

- Process management
- Memory management
- File system
- Device management
- Network management

### Two views of an OS

#### Extended machine

- Hardware is too complex for most computer users to understand.
- OS provides users with an equivalent of an extended or virtual machine that is easier to use.

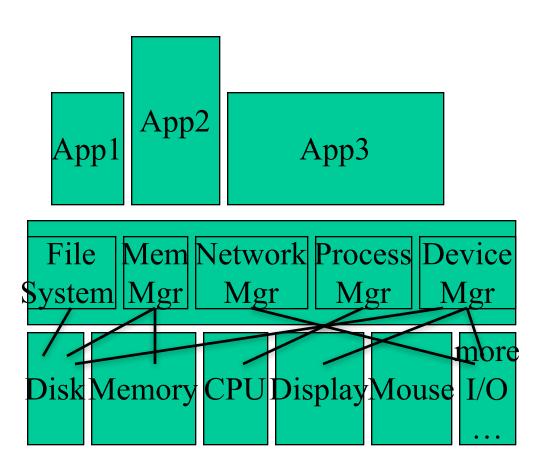

#### Resource manager

- A computing system is comprised of many resources: processors (CPUs), memory, clocks, disks, key board, mouse, monitor, network cards, etc.
- OS allows sharing and effective utilization of these resources.

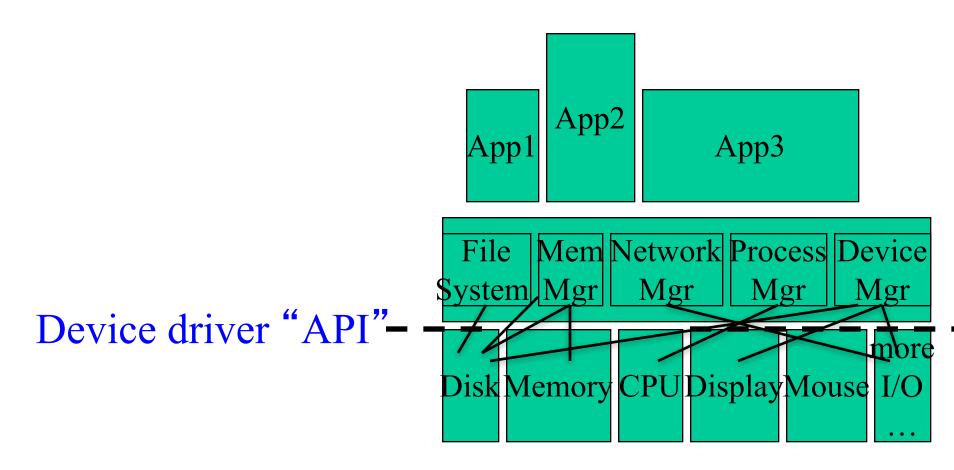

Security and protection

### OS as Resource Manager

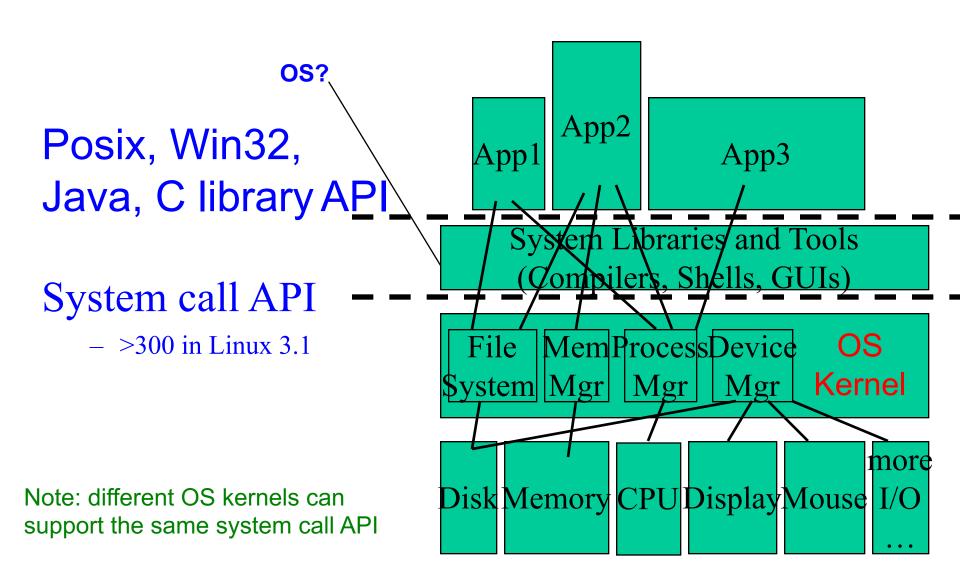

- Process management
- Memory management
- File system
- Device management
- Network management

### OS as Resource Manager

### **Extended Machine View**

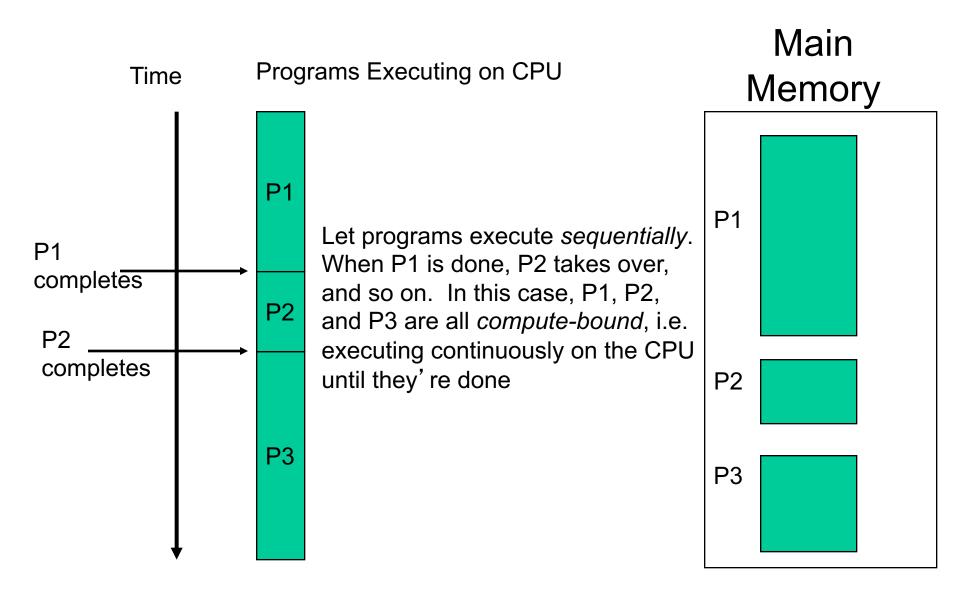

### Evolution of OS

- 1940's and 50's
  - Vacuum tubes
  - Single user
  - No programming language: machine language
  - Used for straight-forward numerical calculations
  - Single program
  - No OS
- mid 50's and early 60's
  - Transistors (more reliable, smaller in size, cheaper)
  - Punch cards
  - FORTRAN
  - Used for scientific and engineering calculations.
  - Batch processing

### Batch Processing

- Execute a pre-defined collection of programs (jobs) called a batch.
- No human interaction

### **Batch Processing**

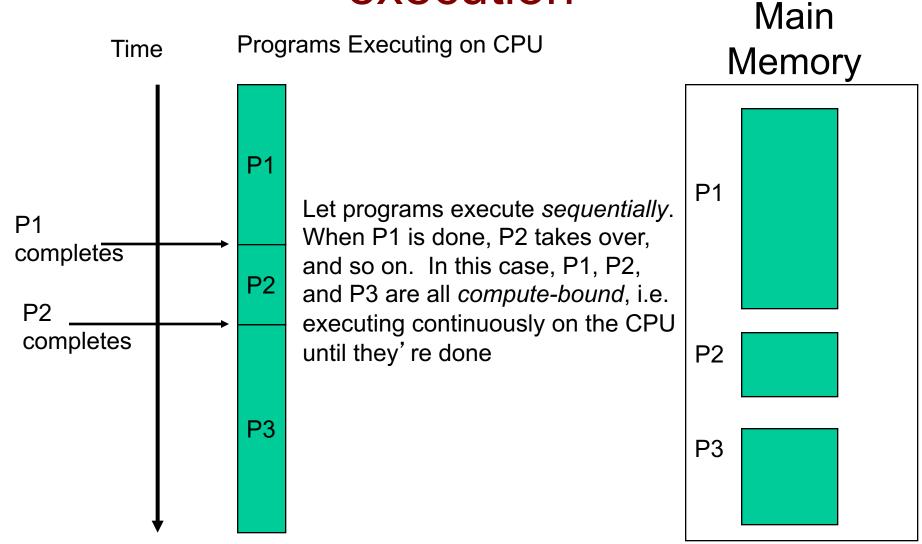

# Limitations of Batch Processing

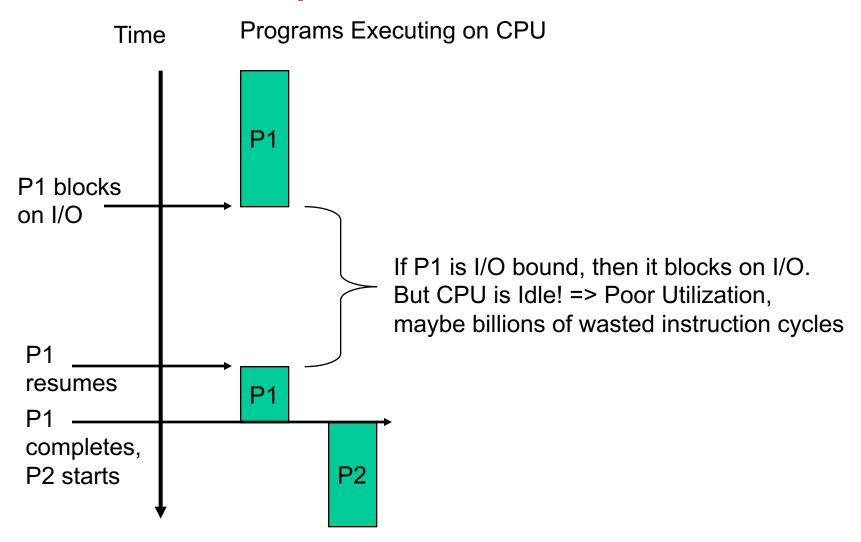

Batch jobs are very non-interactive

- mid 60's to mid 70's
  - Integrated circuits.
  - Multiprogramming: When CPU is idle, e.g.
     when the running program is blocked for an I/O, start another program.
  - Multitasking: Switch CPU between different programs irrespective of whether the running program is blocked.
  - Examples: CTSS, IBM 360, Multics, Unix

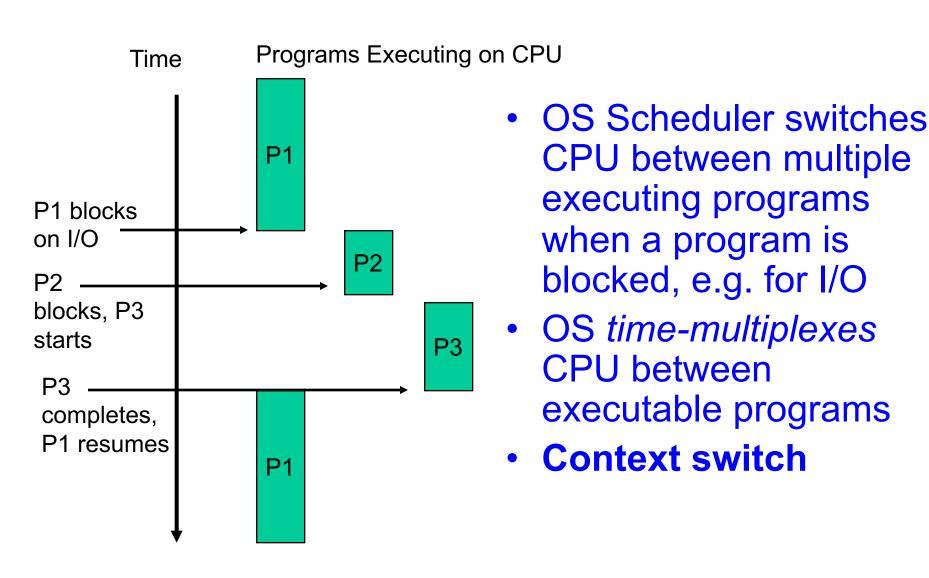

# Multiprogramming: sequential execution

# Multiprogramming: Problem with sequential execution

### Multiprogramming

### Context Switch

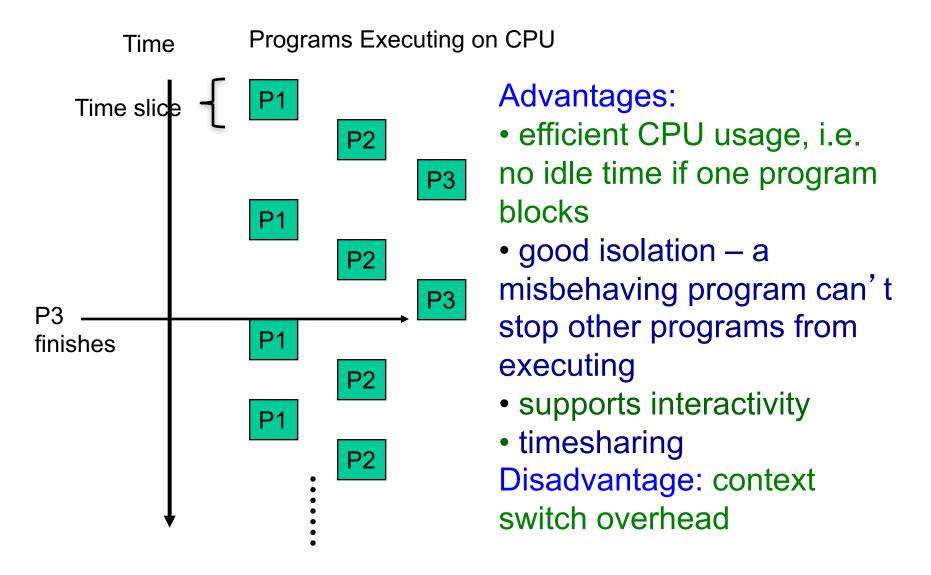

- Switching CPU from one running program to another is called a context switch
  - Save the current state (PC, IR, data registers, stack pointers, etc.) of the running application
  - Load the state of the new application
  - there is overhead due to this context switching
- No useful progress occurs for any applications while the OS is context-switching the CPU.

### Problem with pure multiprogramming

- A CPU-bound program may delay the execution of other programs
  - A program with an infinite loop
  - A program to calculate the value of *pi* to the onebillionth decimal place

### Multitasking

CPU rapidly switches between programs

# Cooperative vs Preemptive Multitasking

- In cooperative multitasking, programs quickly and voluntarily yield CPU before they're done
  - Early OSs did this (Windows 3.1, Mac OS 9.\*)
  - Poor fault isolation due to misbehaving programs
- In preemptive multitasking, OS forces programs to give up CPU
  - Fault isolation, interactivity, efficient CPU utilization
  - Time slice: time interval for which a program is allowed to run at any time
- All modern OSs are preemptively multitasked
  - Linux, BSD Unix, Windows NT/XP/Vista/7, Mac OS X 10.\*

### Preemptive Multitasking

- How does OS force rapid switching?
  - Timer interrupt fires periodically
  - This suspends execution of the currently executing program and returns control to the OS scheduler (another program)
  - The scheduler decides the next program to execute and loads it, then passes control to it
- Context switch overhead: If you choose your default time slice too small, then you'll incur a lot of context-switching overhead as a % of your overall CPU utilization.

- mid 70's to 90's
  - LSI/VLSI; LANs
  - PCs and workstations
  - Process control and real-time systems
  - User friendly software
  - Distributed operating systems
  - MS DOS, 4.2 BSD Unix with TCP/IP, Mac OS with GUI, Linux, ...

### OS Design

- OS design is guided by two factors:
  - Technology: processor, storage,
     communication, new I/O devices, ...
  - Application needs

### Operating System: Current Trends

- Hardware has evolved quickly OS must adjust
  - Moore's Law roughly applies to CPU speed and/or memory size: doubles every 18 months => exponential!
    - Enables complex modern operating systems like Linux, Windows, UNIX, OS X

#### Storage Evolution:

Punch card stores code 1950s-80s

Tape Drive 1950s-80s

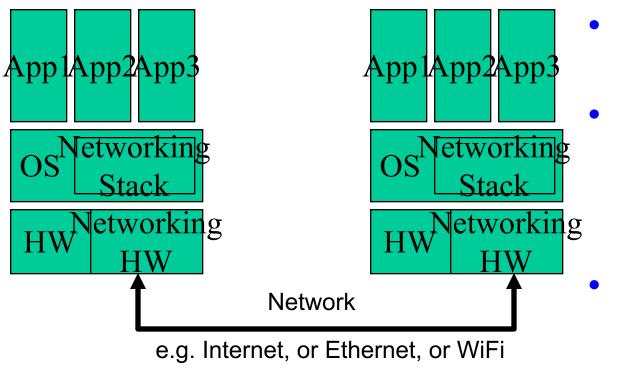

Disk Drive 1960s-2000s

Flash Drive already at 16 GB @ \$30 => OS disk scheduling obsolete??

But Moore's Law doesn't apply to disk access speed or to battery life

### Distributed operating systems

- Examples:
  - App1 is a distributed client server app,
     e.g. App1 on left is Web browser,
     App1 on right is Web server

- Networked File System
- OS adds TCP/IP Network Stack
- Device driver support for Networking cards

### Operating System: Current Trends

- Diversification of OS's to many different target environments
  - Energy-efficient cell phone OSs scaling down
    - iPhone's iOS, Google's Android, ...
  - Multi-processor OSs scaling up
    - Adapting Linux and Windows to multiple cores.
       Massively parallel supercomputers.
  - Real-Time OS for Embedded and Multimedia Systems
    - VXWorks, robotic OSs, ...

### Operating System: Current Trends

- Virtualization Virtual Machines (VMs)
  - Running a Windows VM inside a Linux OS, and vice versa.
  - More layers of abstraction
- Cloud computing rents VMs on racks of PCs at a massive scale
   Google Data Center in The Dalles, Oregon
